

Investor Intelligence Dashboard

Complete Power BI Project Documentation — Cleaning, Power Query, DAX, Visuals, URLs, Design & Interview Explanation

Purpose: A complete record of the dashboard build from two raw investor sources through Excel preparation, Power Query transformation, DAX measures, URL handling, dashboard construction and interview explanation.

Source-code note: The exact complete M scripts and full VBA GetHyperlink implementation were not preserved in the conversation record. This document therefore records the verified workflow and formulas without inventing missing code.

1. Project Objective

The goal was to build an interactive Investor Intelligence Dashboard that consolidates investor information from two sources: Website research and LinkedIn connections.

Main business questions

How many unique investors exist? How many came from each source? Which companies have the most investors? Which countries contain the most investors? How complete are company and email fields? Can users open company websites and LinkedIn profiles directly?

2. Source Data

Investors / Website

Investor records collected from websites, including FULL NAME, Role, Company Name, Email, Country and company/LinkedIn information.

LinkedIn

Investor records from LinkedIn connections, including FULL NAME, COMPANY NAME, EMAIL, PHONE NUMBER and invitation/LinkedIn-related fields.

Post-cleaning row counts

Website/Investors: 255 rows. LinkedIn: 189 rows. Appended table: 444 rows.

3. Cleaning Principles

A missing field did not automatically make an investor invalid. Records with a valid investor name but missing email, company, country or LinkedIn URL were retained. Completely blank/unusable records were removed.

This matters because filtering one column for null can delete an otherwise valid investor record.

4. Hyperlink Extraction

The original Excel data contained clickable hyperlinks. To make the URLs usable in Power BI, a VBA helper function named GetHyperlink was used to return the URL behind a cell.

```
=GetHyperlink(D2)
```

The extracted targets were stored in Company_URL and LinkedIn_URL columns and filled down rather than copied manually.

5. Power Query Source Preparation

The main queries were Investors, LinkedIn and the final Append1 master query. Merge1 was created temporarily but was not used for the final consolidation.

Name-cleaning helpers

Investors: FULL NAME was duplicated into Investors Name and cleaned. LinkedIn: a FullName_Clean helper was created and cleaned.

Duplicating the field preserved the original source value while allowing cleaning.

6. Merge vs Append

Merge combines columns based on a matching key. Append stacks rows from similar datasets. Because the requirement was to retain all Website and LinkedIn investors rather than match the same people, Append was the correct operation.

7. Append1 — Final Master Table

Append1

Final eight columns

1. Full Name 2. Role 3. Company Name 4. Email 5. Country 6. Company_URL 7. LinkedIn_URL 8. Investors Source
Append1 contains 444 rows. The dashboard KPI counts 432 distinct investor names.

8. Unified Full Name

After append, the helper name fields had different names and therefore showed nulls for the opposite source. A temporary Full Name Final column was created with:

```
if [Investors Name] <> null then [Investors Name] else [FullName_Clean]
```

After confirming the original appended FULL NAME already contained both source populations, Full Name Final was removed and the appended field was renamed Full Name.

9. Investors Source

A source-classification custom column was created using:

```
if [Investors Name] <> null then "Website" else "LinkedIn"
```

This identifies each row as Website or LinkedIn and powers source filtering, source KPIs and the source distribution chart.

10. Phone Number and Invitation Fields

Phone Number was removed from the final eight-column structure. An invitation field was temporarily tested as True/False, but values such as Cannot remember caused type errors; the conversion was undone rather than forcing incompatible values.

11. URL Configuration

Company_URL and LinkedIn_URL were categorized in Power BI as Data category → Web URL. The table was designed to show readable names instead of long raw URLs, with the URL fields providing the navigation targets.

12. DAX Measures

Total Investors

```
Total Investors = DISTINCTCOUNT(Append1[Full Name])
```

Website Investors

```
Website Investors = CALCULATE( DISTINCTCOUNT(Append1[Full Name]), REMOVEFILTERS(Append1[Investors Source]),  
Append1[Investors Source] = "Website" )
```

LinkedIn Investors

```
LinkedIn Investors = CALCULATE( DISTINCTCOUNT(Append1[Full Name]), Append1[Investors Source] = "LinkedIn" )
```

Email Coverage %

```
Email Coverage % = DIVIDE( CALCULATE( COUNTROWS(Append1), Append1[Email] <> BLANK() ), COUNTROWS(Append1) )
```

Company Coverage %

```
Company Coverage % = DIVIDE( CALCULATE( COUNTROWS(Append1), Append1[Company Name] <> BLANK() ), COUNTROWS(Append1)  
)
```

Function meanings

DISTINCTCOUNT = unique investors. CALCULATE = changes filter context. REMOVEFILTERS = removes the source slicer for the Website-specific measure. COUNTROWS = counts records. DIVIDE = performs the coverage ratio. BLANK = tests for missing values.

13. Why 444 Rows but 432 Investors?

The appended table has 444 rows, but DISTINCTCOUNT(Full Name) returns 432. The business KPI was intended to represent unique investors rather than raw rows.

Website source rows: 255. LinkedIn source rows: 189. Total appended rows: 444. Website distinct investors: 244. LinkedIn distinct investors: 188. Total distinct investors: 432.

14. Dashboard Filters

Investors Source slicer: Website, LinkedIn, or cleared/All view. Country slicer: filters the dashboard geographically.

15. Dashboard Visuals

Top 10 Companies — clustered bar chart using Company Name and investor count, filtered to Top 10; blank company values excluded from the visual.

Investors by Country — clustered bar chart showing investor distribution by country.

Investor Source Distribution — donut chart comparing Website and LinkedIn using distinct investor counts.

Investor Explorer — detailed table containing Full Name, Role, Company Name, Country and Email, with readable clickable investor/company fields.

16. Why the Top-10 Chart

It answers a specific business question: which companies have the highest number of investors in the database? A Top N filter was used to keep the visual focused.

Blank Company Name was excluded from the visual only. The underlying investor records were not deleted.

17. Investor Explorer

The table is the operational/detail layer. After summary charts identify a useful segment, the user can inspect an individual investor, their role, company, country and email, and navigate to the relevant web/LinkedIn destination.

18. Dashboard Design

The canvas uses a clean white-to-soft-mint/teal background with subtle geometric curves, waves and dotted patterns. The background is intentionally quiet so data remains the focus.

A small investment-themed logo was added in the upper-left corner and the dashboard title was set to Investor Intelligence Dashboard.

19. Current KPI Snapshot

Total Investors: 432 Website Investors: 244 LinkedIn Investors: 188 Company Coverage: 97% Email Coverage: 78%

20. Technical Architecture

RAW DATA | +-----+ | Investors LinkedIn | | +-----+-----+ | Power Query | Cleaning / Transformation | Append | Append1 |
Power BI Model | DAX Measures | KPIs + Visuals | Investor Intelligence Dashboard

21. Power Query vs DAX

Power Query prepares the data: import, cleaning, transformation, null handling, helper columns, custom columns and append. DAX analyzes the data: measures, unique counts, coverage calculations and filter-context calculations.

Interview shortcut: Power Query prepares the data; DAX analyzes the data.

22. Client Use Cases

The client can see unique investor volume, compare source populations, filter by country, identify top companies, inspect geographic distribution, monitor data completeness, browse individual investors, and open company/LinkedIn links directly.

23. Skills Demonstrated

Excel: data preparation, formulas, hyperlink extraction and VBA helper function. Power Query: import, cleaning, null handling, helper columns, custom columns, Append and source classification. Power BI: cards, slicers, charts, tables, URL handling and dashboard design. DAX: DISTINCTCOUNT, CALCULATE, REMOVEFILTERS, COUNTROWS, DIVIDE, BLANK and filter context. Business analysis: KPI design, data-quality monitoring, source comparison, geographic and company analysis.

24. Key Concepts to Memorize

1. Power Query = data preparation. 2. DAX = analytical calculations. 3. Append = stack rows. 4. Merge = combine columns using matching keys. 5. DISTINCTCOUNT = unique investors. 6. Investors Source = Website vs LinkedIn classification. 7. 444 rows does not equal 432 unique investors. 8. Company_URL and LinkedIn_URL are

25. Completion Checklist

automatically justify deleting an investor. 10. Every

26. Completion Checklist

☐ Source datasets imported ☐ Blank/unusable records reviewed ☐ Investor names cleaned ☐ URL fields extracted ☐ Company_URL created ☐ LinkedIn_URL created ☐ Phone Number removed from final structure ☐ Invitation-field type issue handled ☐ Investors and LinkedIn appended ☐ Append1 created ☐ Investors Source created ☐ Final eight-column structure established ☐ URL fields categorized as Web URL ☐ Total Investors measure created ☐ Website Investors measure created ☐ LinkedIn Investors measure created ☐ Email Coverage % measure created ☐ Company Coverage % measure created ☐ Country slicer added ☐ Investor Source slicer added ☐ Top 10 Companies visual added ☐ Investors by Country visual added ☐ Investor Source Distribution visual added ☐ Investor Explorer table added ☐ Clickable company/LinkedIn navigation configured ☐ Background added ☐ Logo added ☐ Dashboard title added
